PREDICTORS OF ONE YEAR SURVIVAL AMONG CHOP-TREATED CHILDREN WITH ENDEMIC BURKITT LYMPHOMA IN LILONGWE, MALAWI

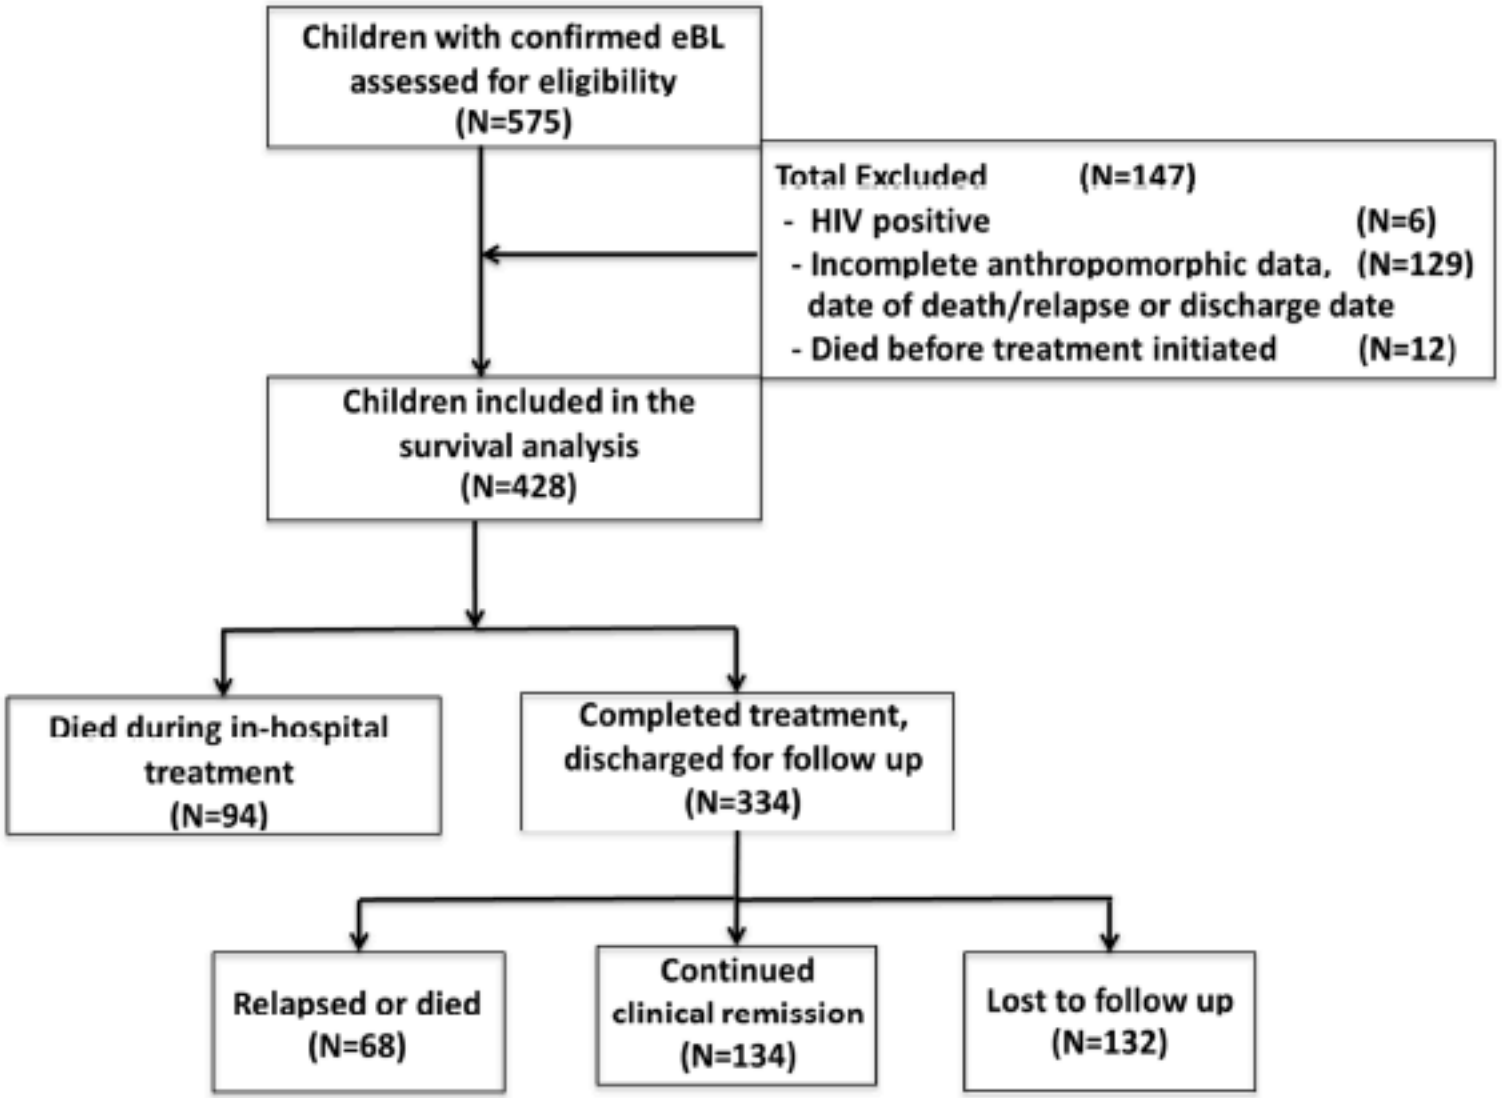
Objective To describe 12-month overall survival (OS) for endemic Burkitt lymphoma (eBL) treated with CHOP in Lilongwe; and examine risk factors associated with 12-month OS.
Method Children ≤18 years with newly diagnosed, pathologically confirmed eBL were enrolled in June 2013–March 2015 in the prospective Kamuzu Central Hospital (KCH) Lymphoma Study. During this period, staging and supportive care were standardized, as was treatment with COP prephase followed by CHOP for 6 cycles as tolerated. Children were actively traced when lost. We assessed 12-month Kaplan-Meier OS, and risk factors for mortality using adjusted Cox proportional hazards. Follow-up was calculated from enrollment until death or loss to follow-up.
Results Sixty-two children with eBL were treated with CHOP between June 1, 2013 and March 31, 2015. Median age was 8.7 years (IQR 6.8-11.3), 40 (65%) were male, and 1 was HIV-infected. Forty-nine (79%) presented with stage III/IV disease, 27 (44%) with abdominal disease, 51 (81%) had Lansky performance score ≤70, and 19 (31%) weight-for-age z-score <–2. Baseline median white blood cells were 8.6 x 103/μL (IQR 6.6–12.5), absolute neutrophils 4.2 x 103/μL (IQR 2.7–6.8), hemoglobin 9.9 g/dL (IQR 8.6–11.3), platelets 448 x 103/μL (IQR 310–599), albumin 3.4 g/dL (IQR 2.9–3.9) and lactate dehydrogenase (LDH) 696 IU/L (IQR 381–1415). As of March 31, 2015, 6 (9.7%) patients were lost to follow-up and estimated 12-month OS was 35% (95% CI 22–51%). Mortality was associated with age >median (HR 2.1, p=0.04), weight-for-age z-score <–2 (HR 2.0, p=0.06), LDH >median (HR 2.3, p=0.03), and performance status ≤70 (HR 3.2, p=0.05). Of 32 deaths, 17 were attributed to disease progression, 11 treatment, and 4 uncertain causes.
Conclusion Compared to published experience using less intense regimens, CHOP did not clearly improve outcomes for mostly advanced eBL in Lilongwe. However, CHOP may be appropriate for some children, and adjudicated deaths were more often due to disease than treatment. Older age, low weight, and higher LDH were associated with worse 12-month OS. Better risk stratification to more appropriately match higher treatment intensity to higher-risk children would likely improve outcomes.



Children with confirmed eBL assessed for eligibility (N=575)
Total Excluded (N=147)
- HIV positive (N=6)
- Incomplete anthropomorphic data, date of death/relapse or discharge date (N=129)
- Died before treatment initiated (N=12)
Children included in the survival analysis (N=428)
Died during in-hospital treatment (N=94)
Completed treatment, discharged for follow up (N=334)
Relapsed or died (N=68)
Continued clinical remission (N=134)
Lost to follow up (N=132)
